Unnamed+

Websites and web applications built around business goals.

We combine product design and software engineering to help companies generate inquiries, communicate clearly, and simplify how work gets done.

Websites · Web applications · Company profiles

Your website should make your business easier to understand, trust, and contact.

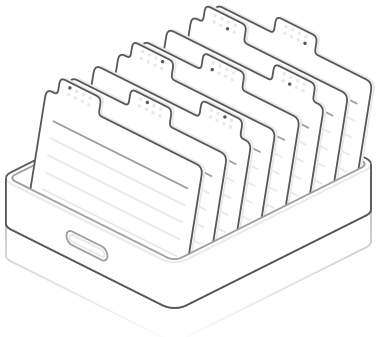

A company can grow faster than its digital presence. The business improves. The team grows. The offering becomes more capable. But the website stays the same.

The business has changed. The website has not.

An outdated website can make an established company look smaller, less capable, or less relevant than it actually is.

People visit, but do not know what to do next.

A website can contain all the right information and still make it difficult to request a quote, contact sales, find a product, or understand why the company is worth considering.

The internal team does not have the capacity to rebuild it.

Marketing, IT, and management already have their own priorities. A website project needs someone to turn business requirements into structure, design, working software, and a finished launch.

That is where we work.

What we take on

- Working out what the product needs to achieve
- Designing the interface and the paths through it
- Handing over access, documentation, and support
- Structuring the information people have to understand
- Building and shipping the working product
- Keeping the decisions written down and reviewable

What we need from you

- Someone who can answer questions about the business
- A decision maker for the review points
- Access to the material that already exists
- An honest view of the constraints

Most projects start because something concrete is not working: inquiries arrive without the information sales needs, buyers cannot tell which product fits them, or a process is being held together by hand.

Where projects usually start

- The website describes the company, not the buyer’s problem
- The product range is filed the way the company files it
- A process depends on one person’s spreadsheet
- Sales answers the same questions on every call
- Proof exists but is not where the claim is made
- The last rebuild was never finished

We start with what the business needs the product to do.

Before deciding how a website should look, we define what it needs to help people understand or accomplish.

Generate inquiries

Make it easier for potential customers to find the right information and contact sales.

Explain the business clearly

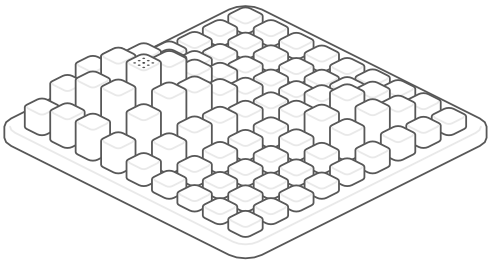

Turn complex products, services, and capabilities into information people can understand.

Build credibility

Present the company, its work, facilities, certifications, and experience with the level of clarity the business deserves.

Reduce manual work

Build web applications and internal tools that simplify repetitive processes and fragmented workflows.

Four disciplines, one project.

Business context → Product thinking → Design → Engineering

The order matters. Business context sets the constraints. Product thinking decides what to build and what to leave out. Design makes it understandable. Engineering makes it real, and it starts before design is finished, because feasibility is a design input rather than a later objection.

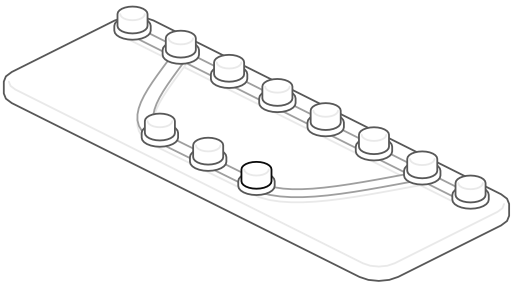

The goal is not simply to deliver pages.

The goal is to build something useful to the business and usable by the people it serves. Those are two different tests, and a project has to pass both.

What keeping the four in one team changes

- No handover where the reason for a decision disappears
- No design that turns out to be unbuildable after approval
- Design decisions made with performance and content in view
- Technical decisions made with the user in view

It also changes what we say no to. If a feature cannot be built well within the scope, we would rather take it out of this phase and write it down than ship something we will have to rebuild.

What we build

Websites

Corporate websites, product websites, and campaign sites designed around clear business actions. From information architecture and interface design to development, CMS, analytics, and launch.

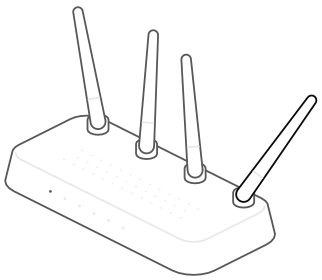

Web applications

Custom tools, dashboards, portals, and workflow applications built around a specific operational need. From product definition and interface design to software engineering and deployment.

Company profiles

Printed and digital company profiles that make a business easier to understand, evaluate, and remember. From information structure and writing to visual design and print-ready production.

Most engagements mix the three. A corporate website often needs a quotation workflow behind it. A company profile usually needs a digital version that doubles as a landing page.

The deliverable changes. The goal stays clear.

Our work usually needs to help a business do one or more of three things.

Convert

Turn attention into a business action.

- Inquiry
- Request for quotation
- Sales contact
- Meeting
- Application
- Distributor inquiry

Communicate

Make important information easier to understand.

- Capabilities
- Products
- Services
- Experience
- Certifications
- Company credentials

Operate

Make work easier to manage.

- Internal workflows
- Data entry
- Reporting
- Approvals
- Customer portals
- Operational tools

We define the intended outcome before deciding what to build.

How we choose, in four questions

- What outcome, in one sentence a stakeholder would recognise
- What we will look at to decide whether it worked
- Who has to act for it to happen, and what they need to know first
- The smallest product that reaches the outcome, and what waits

Where a client has analytics, we plan against real numbers. Where they do not, we say so, and we measure what the product itself can show: task steps, content coverage, response times, and the paths people take.

Design and engineering stay in the same team.

Unnamed+ is a compact design and engineering studio. We keep product thinking, design, and software development close together.

Direct access to the people doing the work

The people discussing the problem are also involved in designing and building the solution. There are fewer layers between a business requirement and the person responsible for turning it into a working product.

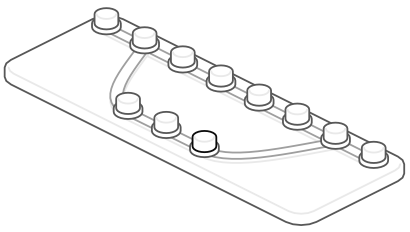

Design with technical context

Design decisions consider feasibility, performance, content, and implementation from the start. What can be built well, what costs more than it returns, and what will be hard to maintain are answered while the design is still moving.

Engineering with user context

Technical decisions consider how people will actually use the product, not only whether the feature works. A form that saves correctly but reads badly has not solved the problem it was built for.

Fewer handoffs. Clearer ownership.

A compact core team

We keep the core team small and extend it with trusted specialists when a project requires additional expertise. This gives each project clear ownership without pretending every problem needs a large agency team.

What stays inside the core team

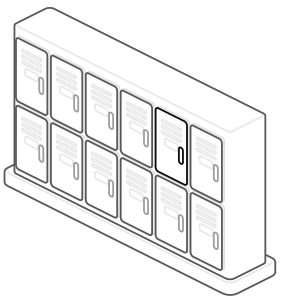

- Product definition and scope
- Information architecture and content structure
- Interface design and the visual system
- Front-end and back-end engineering
- Deployment, handover, and support

What we bring in when it is needed

- A particular platform or integration
- Print specification and production
- Security review
- Data migration
- Photography or illustration

The project still has one accountable core team. Specialists are brought in for a defined piece of work, and we tell you when a specialist is being added, what they are doing, and what it costs.

Fewer handoffs. Clearer ownership.

A clear process from problem to launch

01 Understand

We learn about the business, audience, current problems, constraints, and intended outcomes.
Output: project context and success criteria.

02 Define

We turn those requirements into scope, information architecture, technical requirements, milestones, and responsibilities.
Output: a clear project plan.

03 Design

We develop the content structure, user experience, interface, and prototypes needed to validate the direction.
Output: an approved product direction.

04 Build

We turn the approved design into a working website or application, in reviewable increments.
Output: a production-ready product.

05 Validate

We review functionality, responsiveness, content, browser compatibility, performance, and launch requirements.
Output: a tested release.

06 Launch and support

We deploy the product, hand over the required access and documentation, and support the team after launch.
Output: a working product your team can continue using.

Every stage has something you review and something you receive, so progress is visible rather than reported.

What you get at each stage

- Before production: scope, responsibilities, review points, and timelines in writing
- During production: work reviewed at defined stages, in a form you can open
- Before launch: functionality, content, browsers, devices, and performance signed off
- At launch: deployment, redirects, analytics, and a checklist
- At handover: source files, code, credentials, assets, and documentation
- After launch: support defined in advance, with who to contact

iMOW Indonesia

An industrial product range that a buyer could not evaluate without talking to a sales representative first.

Industry	Engagement	Scope
Material handling and industrial equipment	Corporate website and product platform	Strategy · Information architecture · UX · UI · Development · CMS

The context

iMOW sells electric forklifts and material handling equipment in Indonesia: diesel trucks, lead-acid and lithium battery forklifts, stackers, reach trucks, pallet trucks, order pickers, and tow tractors. The range is technical, the buyers are operational, and the decision is expensive enough that nobody makes it from a single page.

The problem

Products were listed by model name rather than by the job they do, so a buyer arriving with an operational question had to translate it into the company’s internal product language first. Industry context was missing: a cold storage operator and an e-commerce fulfilment centre need different machines, and neither could see themselves on the site. The running cost comparison, the strongest commercial argument the company had, was not available to a visitor at all.

What needed to change

A buyer should be able to discover, evaluate, calculate, and inquire without a sales call. That is four steps, and each one needs its own structure: a product taxonomy that matches how buyers think, industry context and specification detail for evaluation, the cost comparison as a tool rather than a paragraph, and an inquiry path that is obvious at the moment the buyer is convinced.

A buyer should be able to discover, evaluate, calculate, and inquire without a sales call.

What we did

We reorganised the range into eight categories that follow how equipment is chosen: by power source, by handling task, and by application. We built four industry pages. We designed and built a total cost of ownership calculator that takes a buyer’s fleet size and daily operating hours and returns an estimate of the saving against diesel or lead-acid equipment. Finally we structured the commercial paths so each one sits where the buyer is already ready for it.

What we built

- Eight product categories with model pages
- A total cost of ownership calculator
- Bilingual structure: English and Indonesian
- Four industry use case pages
- Quotation, free trial, and catalogue paths
- News and event content

PT Gunung Kendali Docking

Nine kinds of engineering work sold to five industries, which a buyer could not evaluate without booking a consultation first.

Industry	Engagement	Scope
Marine and industrial engineering	Corporate website	Strategy · Information architecture · UX · UI · Development

The context

PT Gunung Kendali Docking works on ships and on industrial plant: vessel docking, main and auxiliary engine repair, gearbox overhaul, boiler inspection and retubing, valve servicing, hydraulic and crane repair, alternator rewinding, electrical automation, and spare parts supply. Its buyers are procurement and technical managers at shipyards, shipping companies, power plants, chemical plants, and heavy equipment operators. They arrive with a machine that has stopped, or a docking window that is already booked.

The problem

A company that does nine kinds of work looks unfocused when the work is presented as a list. The buyer’s first question is not “what services do you offer” but “do you do this job, on this equipment, in this industry”, and the site had no way to answer it quickly. Proof existed but was disconnected from the claims it supported.

What needed to change

Make a technically complex engineering company understandable within a few minutes. Every service line needs a page that says what it covers and who it is for, every industry needs to see its own context, and every claim needs evidence placed next to it. Then the commercial path has to be short, because this buyer is already in a hurry.

Make a technically complex engineering company understandable within a few minutes.

What we did

Each service became its own page with the equipment it covers, the work it involves, and the industries it applies to. We gave the five industries their own context, so a shipyard and a chemical plant read different pages about the same capability, and linked the two sets to each other. We built the proof architecture: partner marks beside the claim of experience, published case studies with the vessel and the work named, and testimonials only where the client has approved the wording.

What we built

- Nine service pages with their equipment and scope
- A partner wall of marine and industrial operators
- A consultation and quotation path on every page
- Five industry contexts, cross-linked with services
- Published project case studies
- An FAQ answering the questions that become first calls

9	5	3	13
Engineering services structured	Industries represented	Published case studies	Named partner marks

The client states that it has worked on more than 100 marine projects since 2021. That is the company’s own figure, presented as theirs. We did not measure it and we do not present it as our result.

Selected work

A selection of websites and digital products we have designed and built.

iMOW Indonesia	Corporate website and product platform	An industrial electric forklift range restructured around the buyer's decision, with a total cost of ownership calculator and three commercial paths.
PT Gunung Kendali Docking	Corporate website	Nine marine and industrial service lines and five industries, structured so a buyer can tell within minutes whether the company does their job.

Further projects are published once each client has approved the wording. We do not describe client work in a way that identifies them anyway, and we do not fill this page with work we cannot show.

Every case study on this page states

- The business problem, in the client's terms
- What needed to change before design was discussed
- What was built, in countable terms
- What was difficult, unclear, inefficient, or outdated
- The decisions we made and why
- The outcome, using only evidence that can be verified

Websites for manufacturing companies

Make it easier for buyers to understand what your company can do.

Manufacturing businesses often need to communicate a large amount of technical and commercial information. A corporate website should help buyers find that information without relying on a sales representative to explain everything first.

Products and specifications

Help buyers find the right product and its technical information.

Request for quotation

Give qualified prospects a clear path to the commercial team.

Manufacturing capabilities

Explain facilities, processes, capacity, machinery, and areas of expertise.

Distributor and export information

Support buyers, partners, and distributors across different markets.

Certifications and standards

Make relevant credentials easy to find and verify.

Company credentials

Present the scale and experience of the business with the clarity it deserves.

Industries served

Show where the company’s capabilities are already being applied.

Where most sites fail

Buyer language, proof separated from the claim, and a quotation path that asks the wrong questions.

Help the right buyer understand the company and take the next step.

A compact multidisciplinary team

Unnamed+ brings product, design, and engineering into one core team.

Product engineer

Product thinking · Interface design · Front-end engineering

Software engineer

Back-end engineering · Infrastructure · Integrations

Product engineer

Product strategy · Software engineering · Technical architecture

UI designer

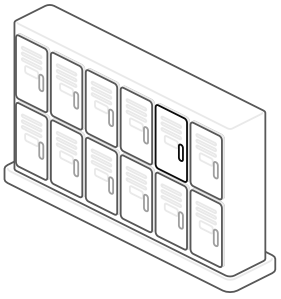

Interface design · Visual systems · Design production

Names and portraits are added when each person has approved how they appear. The roles above describe the work, which does not change.

When a project requires expertise outside the core team, we work with specialists from our trusted engineering network. The project still has one accountable core team.

What stays inside the core team

- Product definition and scope
- Information architecture and content structure
- Interface design and the visual system
- Front-end and back-end engineering
- Deployment, handover, and support
- Accountability for the delivered work

Clear ownership throughout the project

Good work is not enough if the process is difficult to manage.

✓ Defined scope and milestones agreed before production begins

✓ Regular reviews at defined stages, not at the end

✓ Clear handover of source files, code, credentials, and documentation

✓ Semantics, keyboard use, contrast, and reduced motion treated as requirements

✓ One accountable project lead from start to launch

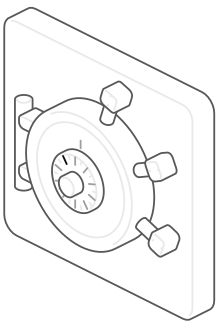

✓ Quality assurance across devices, browsers, content, and performance

✓ Support requirements defined before launch

✓ Findings written down and fixed, not summarised as minor issues

For procurement and vendor onboarding

Company registration, tax, and contract documents are supplied as part of procurement, once they have been verified. We work under your contract or ours, and sign a non-disclosure agreement where the work involves information you do not want shared. You own the delivered work: code, source files, assets, and accounts are handed over or transferred as agreed.

What we publish, and what we refuse to claim.

A studio can describe its work in ways nobody can check. We would rather show fewer numbers and have each one hold up.

What we publish today

- Counts of what was structured, written, designed, and built
- The scope of each engagement
- Client claims labelled as the client's own
- Technical results we measured ourselves

What we do not publish

- Revenue uplift without the client's analytics
- Conversion percentages we cannot support
- Testimonials the client has not approved
- Client logos without permission

Four kinds of evidence, and who can measure each one

- Product output: pages, products structured, languages, features. We can count these today.
- User impact: task time, steps, completion. Measurable in some projects, with the client and their users.
- Technical output: performance, accessibility, page weight, responsive coverage. We measure these with tools.
- Business impact: revenue, inquiries, savings. Requires the client's analytics.

Testimonials and client marks appear here once each client has approved the exact wording and how they are named. Until then the space stays empty rather than filled with something we cannot stand behind. If you would like to talk to a reference, ask us and we will arrange it directly.

Numbers about projects delivered, years of operation, and repeat clients are added when they can be supported. We do not publish a figure until then.

Find out what your website could do better.

We can review your current website and identify where its structure, content, design, or technology may be making it harder for people to understand your business or take action.

The audit covers

- Positioning and message clarity
- Calls to action
- Technical performance
- Information structure
- Mobile experience
- Obvious conversion friction

QR
Audit

Request a website audit

Scan the code or write to hello@unnamed.plus. You get the findings in writing, ranked by what is likely to matter most, with what we would fix first and what we would leave alone. If the site does not need a rebuild, the audit will say so.

Already have a project in mind? Book a 30-minute discovery call, or ask for a proposal.
